(v0.1 released January 2015)

This paper describes the calibrated energy modeling process of a campus of 32 higher education institutional buildings. The campus is modeled at both the building scale using the EnergyPlus simulation engine and at the urban scale using the CitySim engine. A co-simulation framework was created to execute simulations from both engines concurrently with an exchange of various information to leverage the various strengths of each. On-site weather and measured performance data is then compared to the output from three modeling scenarios: building-scale simulation, urban-scale simulation, and co-simulation of the engines. A partial calibration process is implemented to reconcile the simulations with the measured data. The results illustrate that **insert results here**. A discussion is included of the challenges encountered with the urban scale calibration and the strengths and weaknesses of the developed process.

Keywords: Building-scale simulation, Calibrated energy models, CitySim, Co-simulation, EnergyPlus, Urban-scale simulation

1. Introduction

Urban scale building performance simulation is a process that empowers the analysis and optimization of cities. Urban populations are growing around the world at an unprecedented rate. A shift from urban to rural is underway and 2.5 billion people are expected to join urban centers throughout the world (United Nations 2014). Expansions of entire districts and even cities is not an uncommon phenomenon, especially in East Asia and Africa. Urban scale modeling is in the midst of a strong focus within the research community with six key areas of practice: technology design, building design, urban climate, systems design, policy assessment, and land use and transportation (Keirstead, Jennings, and Sivakumar 2012). The ability to simulate the interaction between large collections of buildings enables the development and testing of optimization and planning scenarios for this new development (Dorer et al. 2013).

Here we insert discussion of the strengths and deficiencies of urban scale modeling

Building performance simulation is a mature domain of research relative to the urban scale. **Insert discussion of building-scale simulation**

Here we discuss the benefits of co-simulation

This paper describes the achievement of three novel objectives:

- (1) Automate the process of meta-data extraction from a building information model (BIM) for the creation of both building and urban-scale performance models
- (2) Co-simulate the urban and building scale models through concurrent information exchange

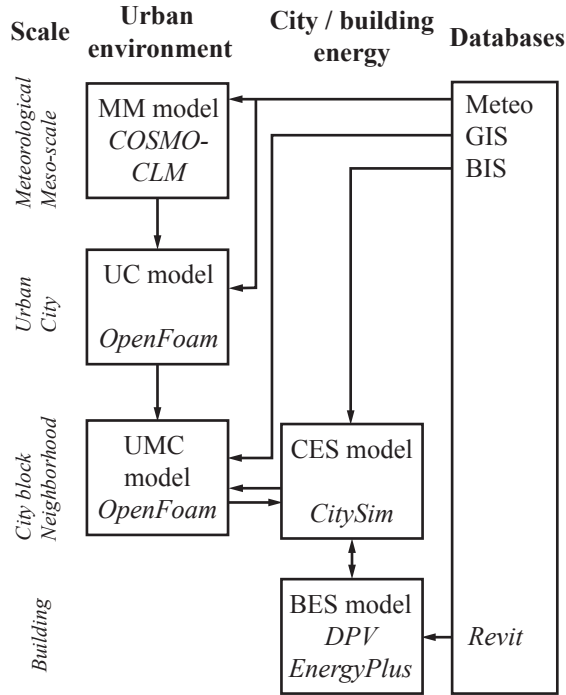

Figure 1. EnergyPlus and CitySim coupling are part of the wider context. Each block in the diagram represents an environment, with the tool/engine name in *italics* (adapted from (Dorer et al. 2013))

- (3) Reconcile the co-simulation output results with the measured energy performance data from the campus energy information system (EIS)

2. Methodology

The research in this paper is part of a larger coupling effort in which various engines are connected and co-simulated to create a more comprehensive analysis of the urban scale (Dorer et al. 2013). The target is the computational interface between the building energy model, using EnergyPlus, and the urban energy model using CitySim. An overview of the larger scope is shown in Figure 1 and the context of the coupling task is shown as the interface between the City Energy Simulation (CES) model and the Building Energy Simulation (BES) model. CitySim is an urban performance simulation engine that comprises a Solver and a Designer (the graphical user interface). It focuses on the energy flows of multiple simplified building models and their interdependent relationship with their urban climate (Robinson et al. 2009). CitySim includes building thermal, urban radiation, occupant behavior, and plant/equipment models integrated as a single simulation engine. To achieve a good compromise between modeling accuracy, computational overheads and data availability, CitySim simulates multiple buildings up to city scale using simplified models. As an example, each building's thermal behavior is based on an electrical analogy using a two node resistor-capacitor network.

The Design Performance Viewer (DPV) is a tool written to extract and simulate an EnergyPlus input data file (IDF) from an AutodeskTM RevitTM BIM (Schlueter and Thesseling 2009). The main philosophy behind the tool is rapid simulation of the building information model from the earliest design possible and can be used throughout the life-cycle of the building including retrofit analysis (Miller et al. 2014). This process is achieved by augmenting the information in the BIM with default values and abstracting information not relevant for energy simulation. The tool already has a simplified notion of surrounding buildings, which are modeled in the BIM as simple mass objects without further information and are exported as shading surfaces to EnergyPlus. This functionality is used for creating the CitySim mass scene and leads to a crude model of the urban context of the building. The existing DPV philosophy of allowing the designer to iterate rapidly on early design

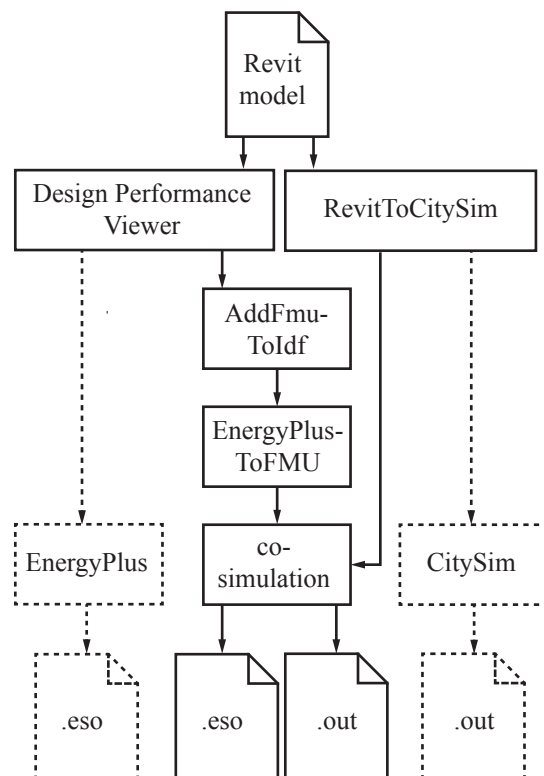

Figure 2. Overview diagram of the coupling process including tools and outputs

decisions based on feedback about the performance of the design remains. This approach includes streamlining the process where running a simulation requires no effort from the designer due to automatic creation of input files, execution and analysis of the results. Since part of the scope of the UMEM project includes coupling a micro-climate simulation with the CitySim software, we couple the weather input to EnergyPlus with CitySim. In return, CitySim receives a more precise simulation of the building's thermal behavior and associated surface temperatures which can be used for the long wave radiation exchange.

2.1. Coupling process

The coupling process of EnergyPlus and CitySim is shown in Figure 2. First, the DPV is used to extract an EnergyPlus simulation model from the BIM. The DPV utilizes the Revit API to extract geometrical information about the building and the physical properties of walls, windows, doors, roofs and floors. This information is encoded in the BIM model as wall types, roof types, floor types as well as window and door families. Wherever possible, the tool uses the layering and materials of the construction types, enhancing them with physical attributes relevant to EnergyPlus. Where not defined, it assumes default values.

Next, geometry is created to be used in both the CitySim and EnergyPlus models as buildings and surfaces surrounding the building targeted in the IDF. This feature of the DPV is used for including shading surfaces in the EnergyPlus simulation model: it uses so-called *mass objects* in the BIM model as surrounding buildings. The DPV model views these buildings as a series of shading surfaces. A transformation is added on the DPV model that produces an input file for the CitySim solver. This file uses an XML format describing the buildings in a scene for simulation, including their construction types, geometry and systems for heating and cooling. The main BIM is extracted to the CitySim scene as one of the buildings to be simulated, with the properties of the construction types matching those in the DPV model. The glazing ratio is calculated based on the window and

Figure 3. Simulation information exchange between CitySim and EnergyPlus using FMI

wall areas of the DPV model. Shading surfaces are grouped into buildings based on the mass object they were extracted from. These neighboring buildings use default construction properties for walls and roofs and we assign them a default glazing ratio. These defaults can be overridden by custom properties applied to the mass objects in the BIM much in the same way as the model elements of the main building are enriched with DPV information.

2.2. Information exchange

As of version 8.1.0, EnergyPlus supports exporting a simulation model as a Functional Mock-up Unit (FMU) (Nouidui, Wetter, and Zuo 2014). This feature introduces new IDF objects to specify the interface such an FMU exposes. These objects define which output variables are exported by the FMU and which variables are imported. The FMU export functionality is closely linked to the Energy Management System (EMS) of EnergyPlus. Co-simulation exchange variables either mimic an EnergyPlus schedule, an EMS variable or drive an EMS actuator. We have found that in order to export an output variable using the FMU export functionality, the variable itself must also be output with an IDF object of type *Output:Variable* or *EnergyManagementSystem:OutputVariable* in the IDF file as well.

Since the model used by CitySim to simulate a building is more abstract than the model used by EnergyPlus, we use the EMS to aggregate certain values. CitySim does not model windows separately, so we calculate a weighted average of window and wall surface temperatures with EMS subroutines.

We automate the process of augmenting the IDF file with the EMS subroutines and FMU export objects. The script *addfmutoidf.py*, written in the Python programming language, uses the *parseidf* module to read in the IDF file and add the new IDF objects based on those found in the model. This script reads in the list of surfaces defined in the IDF file and produces EMS scripts to aggregate and output the surface temperatures of the wall and the windows as well as any other output objects necessary.

The FMU creation process is the basis for coupling the two models at each timestep in the simulation. Figure 3 illustrates this process from both the EnergyPlus and CitySim perspective. We feed the augmented IDF file to the *EnergyPlusToFMI* script (Nouidui and Wetter 2014). This script requires a C compiler and linker. We use Microsoft Visual Studio 12, which is not one of the defaults shipped with the script so we needed to edit the scripts *compile-c.bat* and *link-c-exe.bat* to use the correct path to compiler and linker respectively.

Once configured, the *EnergyPlusToFMI* script produces an FMU file based on the augmented IDF file and the weather file to be used as well as a DLL file implementing the Functional Mock-up Interface that can load the IDF file, locate EnergyPlus and run the simulation. Table 1 and 2 outline the variables exchanged between EnergyPlus and CitySim through the FMI. We used the *fmiilib* library from the JModelica project to test the FMU produced (JModelica 2014). We altered one of the sample programs (*fmi_import_cs.test.c*) to load the FMU, run it and print out the values exported from EnergyPlus. This code was then used as a guide to extending the CitySim solver to load FMUs for co-simulation.

Table 1. Values imported by EnergyPlus from CitySim by the FMU

Object (ep_id)	Variable Name	Description
Outdoor	Outdoor Drybulb	The outdoor dry-bulb temperature in °C
	Outdoor Dewpoint	The outdoor dew-point temperature in °C
	Outdoor Relative Humidity	The outdoor relative humidity expressed in percent.
	Diffuse Solar	Diffuse horizontal irradiance in W/m ²
	Direct Solar	Beam normal irradiance in W/m ²
	Wind Speed	The outdoor wind speed in m/s
	Wind Direction	The wind direction in degrees (N=0, E=90, S=180, W=270)
Zone	Occupation	Fraction of the maximum occupation (0.0-1.0) overrides the EnergyPlus occupation schedule with the CitySim stochastic schedule.

On an hourly basis, CitySim performs a heating and cooling needs prediction step. The temperature determination step for the main building is replaced with the results of the EnergyPlus timestep as obtained through FMI library. We use the FMI library to send climatic and occupational data from CitySim to EnergyPlus (see Table 1), and to receive data from EnergyPlus that are further used within CitySim for the next time steps (see Table 2).

2.3. Co-simulation comparison and calibration

This section will describe in detail the method for comparing the CitySim vs. EnergyPlus vs. Co-simulation and how we use the measured data as a comparison

3. Implementation

3.1. Campus case study

This section will describe the ETH Hoenggerberg case study

3.2. Model development

This section will describe the development of the Revit, CitySim and EnergyPlus models

Table 2. Values exported by EnergyPlus to CitySim by the FMU

Object (ep_id)	Variable Name	Description
Wall, Roof	Outside Surface Temperature	The temperature on the outside of the surface in °C
Wall	Average Outside Surface Temperature	The (weighted) average temperature of the surface on the outside in °C. This respects the temperatures of the windows on the wall, weighted by area.
Zone	Total Heating Energy	The heating energy in Joules used in this timestep.
	Total Cooling Energy	The cooling energy in Joules used in this timestep.
	Zone Mean Air Temperature	The mean air temperature in the zone in °C
	Ventilation Volume Flow Rate	The flow rate in m ³ /s (standard density)

Figure 4. Campus modelled in CitySim

3.3. Measured data collection and processing

4. Results

Here we show all of the data of the comparison between the simulation outputs and the measured data from the campus
